

Scope, Function Calls and Storage Management

Angelo Gargantini

capitolo 7 del
Mitchell

Introduzione

- Quando dichiariamo una variabile, il computer dove la memorizza?
- Quali sono le regole per accedere ad una variabile?

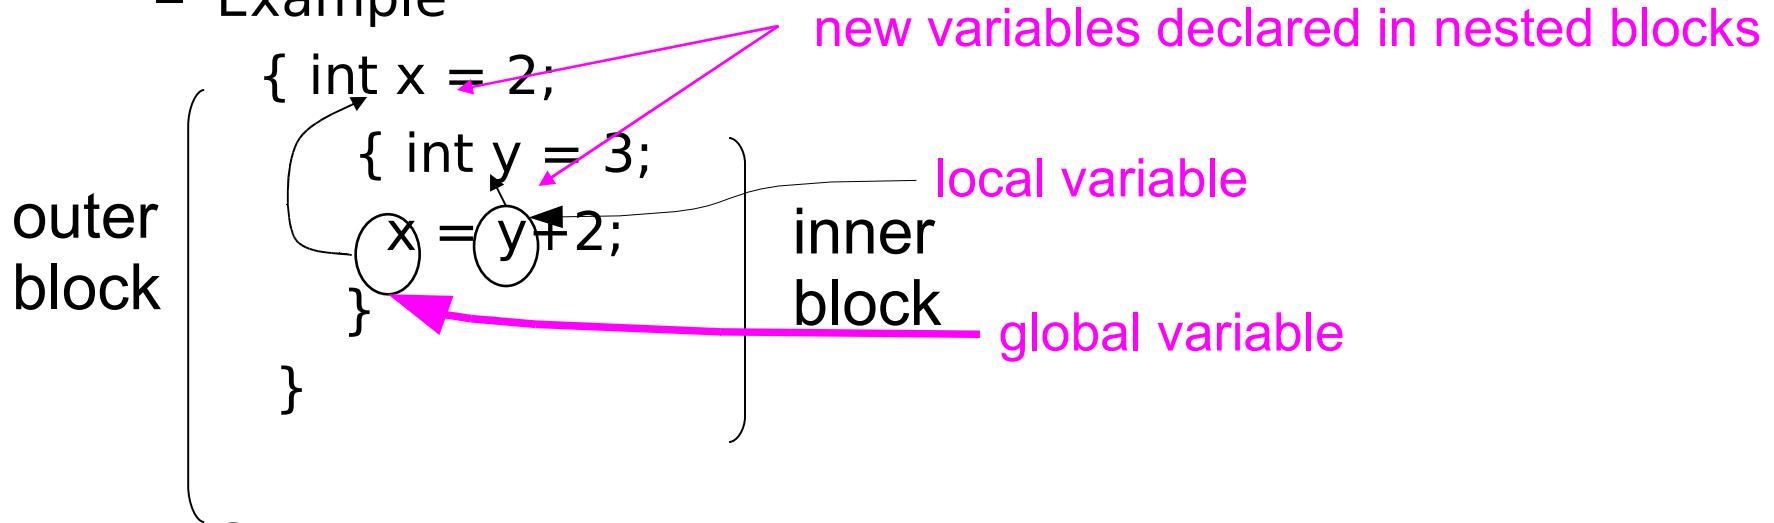

Topics

- Block-structured languages and stack storage
- In-line Blocks
 - activation records
 - storage for local, global variables
- First-order functions
 - parameter passing
 - tail recursion and iteration
- NO - Higher-order functions
 - deviations from stack discipline
 - language expressiveness => implementation complexity

Block-Structured Languages

- Nested blocks, local variables

- Example

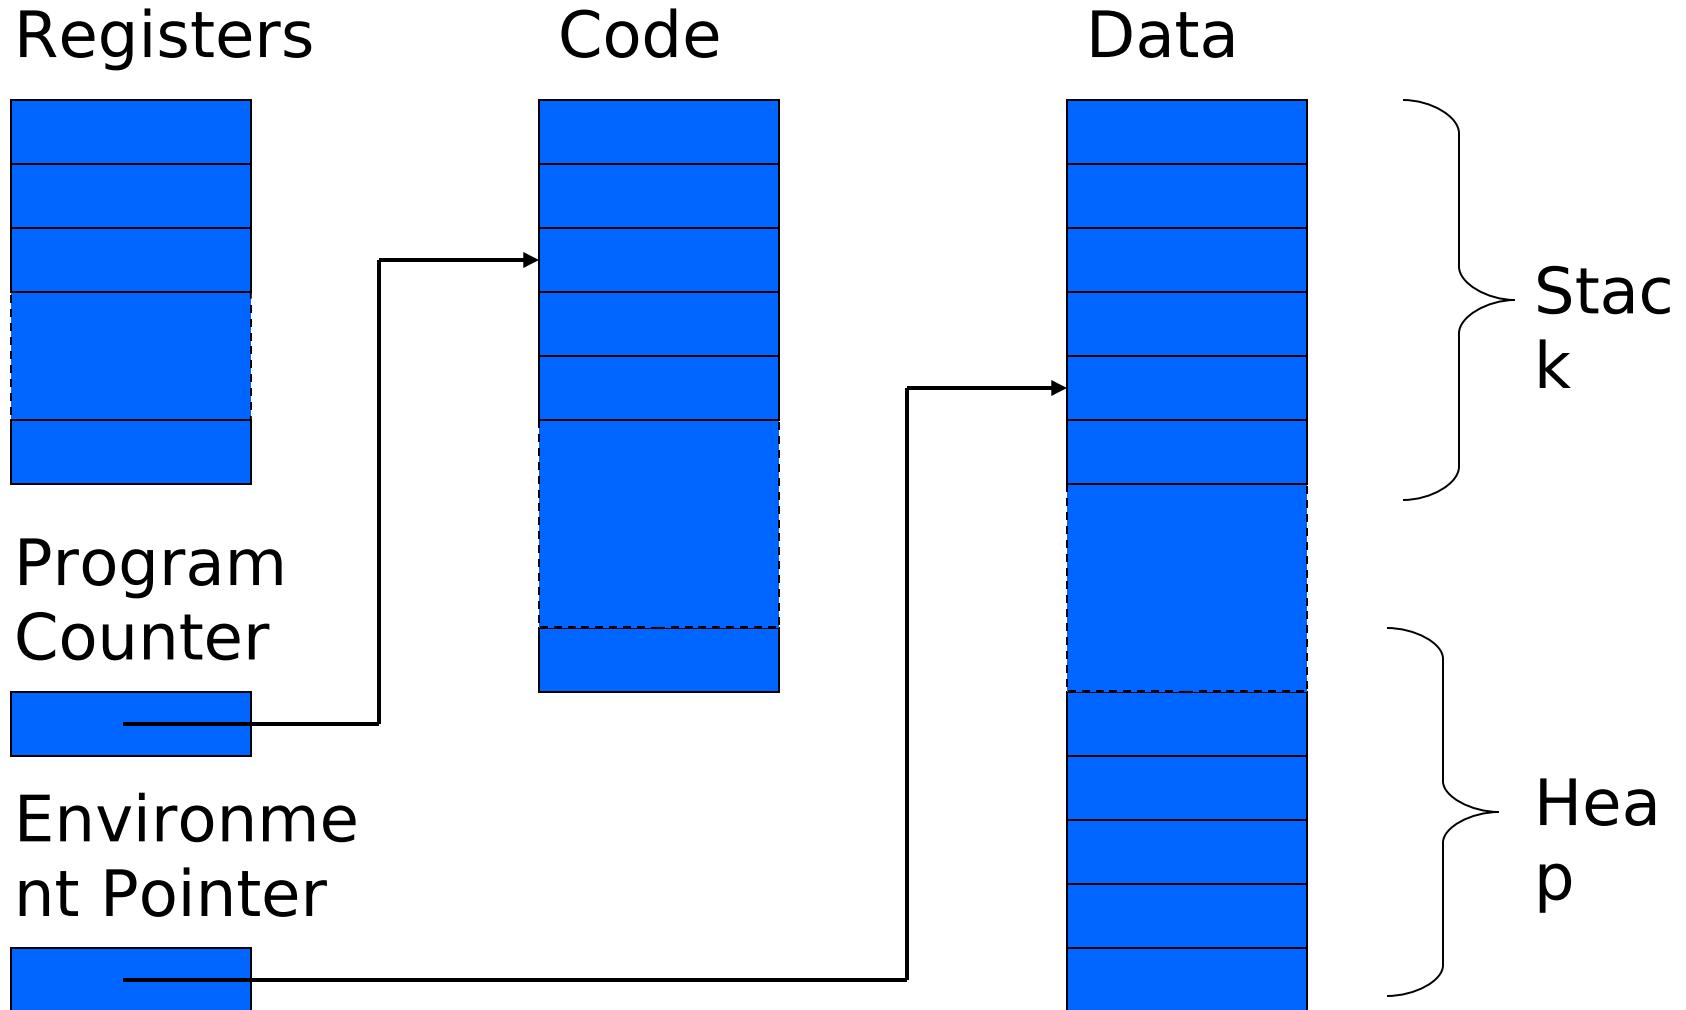

- Storage management

- Enter block: allocate space for variables
 - Exits block: some or all space may be deallocated

Examples

- Blocks in common languages
 - C/c++/Java { ... }
 - Algol begin ... end
 - ML let ... in ... end
- Two forms of blocks
 - In-line blocks
 - Blocks associated with functions or procedures
- Topic: block-based memory management, access to *local variables, parameters, global vars*
- It allows **recursive functions**

Simplified Machine Model

Interested in Memory Mgmt Only

- Registers, Code segment, Program counter
 - Ignore registers
 - Details of instruction set will not matter
- Data Segment
 - Stack contains data related to block entry/exit
 - Heap contains data of varying lifetime
 - **Environment pointer** points to current stack position
 - Block entry: add new activation record to stack
 - Block exit: remove most recent activation record

Some basic concepts

- Scope
 - Region of program text where declaration is visible
- Lifetime
 - Period of time when location is allocated to program

```
{ int x = ... ;  
  { int y = ... ;  
    { int x = ... ;  
      ....  
    };  
  };  
};
```

- Inner declaration of x hides outer one.
- Called “hole in scope”
- Lifetime of outer x includes time when inner block is executed
- Lifetime \neq scope
- Lines indicate “contour model” of scope.

In-line Blocks

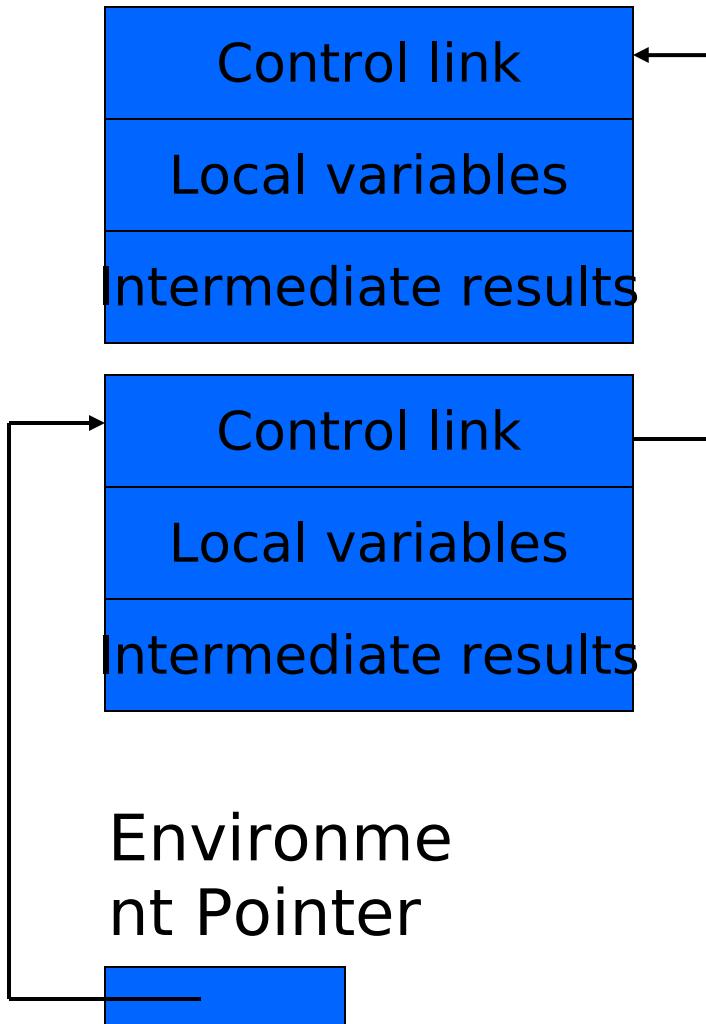

- Activation record
 - Data structure stored on run-time stack
 - Contains space for local variables
- Example

```
{ int x=0;  
    int y=x+1;  
    { int z=(x+y)*(x-  
y);  
    };  
};
```

Push record with space for x, y
Set values of x, y
Push record for inner block
Set value of z
Pop record for inner block
Pop record for outer block

May need space for variables and intermediate results like $(x+y)$, $(x-y)$

Activation record for in-line block

- Control link
 - pointer to previous record on stack
- Push record on stack:
 - Set new control link to point to old env ptr
 - Set env ptr to new record
- Pop record off stack
 - Follow control link of current record to reset environment pointer

Example

```
{ int x=0;  
    int y=x+1;  
    { int z=(x+y)*(x-  
y);  
    };  
};
```

Push record with space for x, y
(set control link = old env
pointer, set env pointer)

Set values of x, y
Push record for inner block
Set value of z
Pop record for inner block
(set env pointer to control
link)

Control link	
x	0
y	1

Control link	
z	-1
x+y	1
x-y	-1

Environment Pointer

Scoping rules

- Global and local variables
 - x, y are local to outer block
 - z is local to inner block
 - x, y are global to inner block

◆ Static scope

- global refers to declaration in closest enclosing block

◆ Dynamic scope

- global refers to most recent activation record

These are same until we consider function calls.

```
{ int x=0;  
int y=x+1;  
{ int z=(x+y)*(x-  
y);  
};  
};
```

Esercizio 7.1

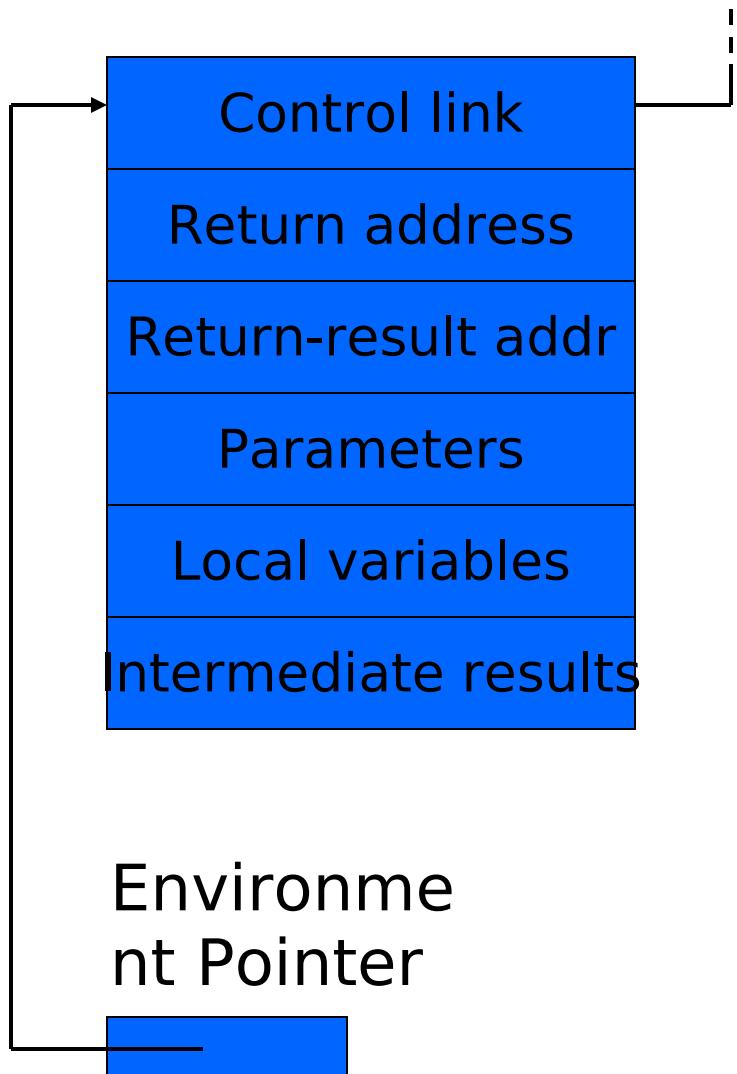

Functions and procedures

- Syntax of procedures (Algol) and functions (C)

```
procedure P (<pars>)      <type> function f(<pars>)
begin                      {
  <local vars>          <local vars>
  <proc body>           <function body>
end;                      };
```
- Activation record must include space for

- parameters
- return address
- return value
 - (and intermediate result)
- location to put return value on function exit

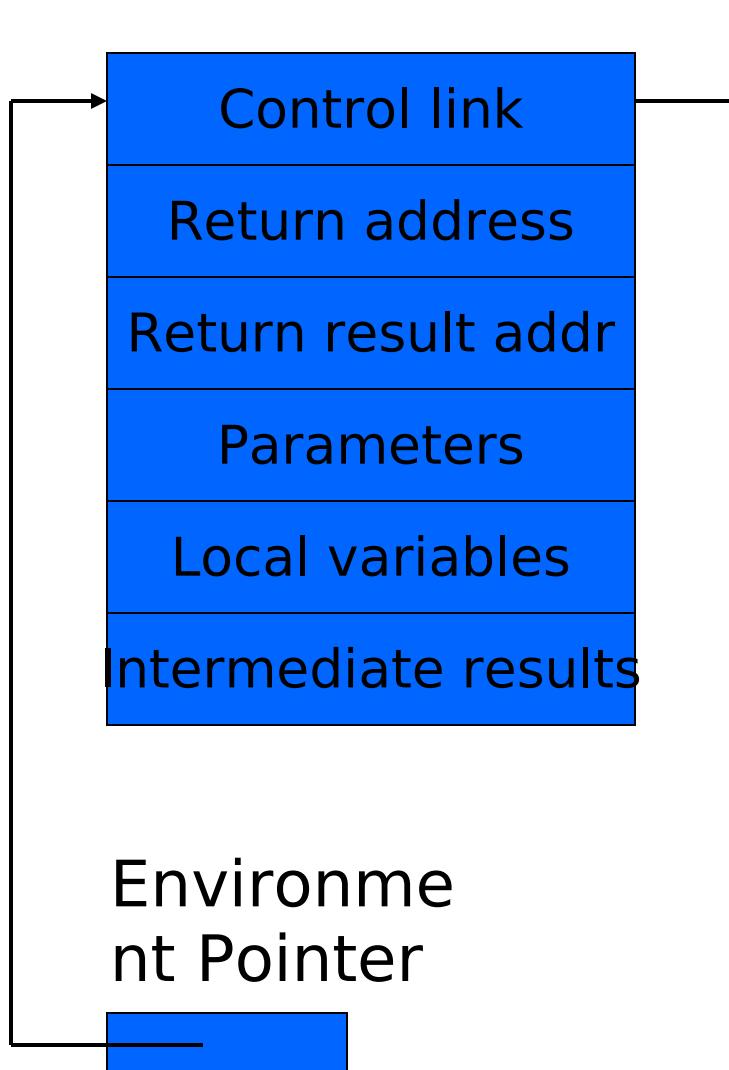

Activation record for function

- Return address
 - Location of code to execute on function return
- Return-result address
 - Address in activation record of calling block to receive return address
- Parameters
 - Locations to contain data from calling block

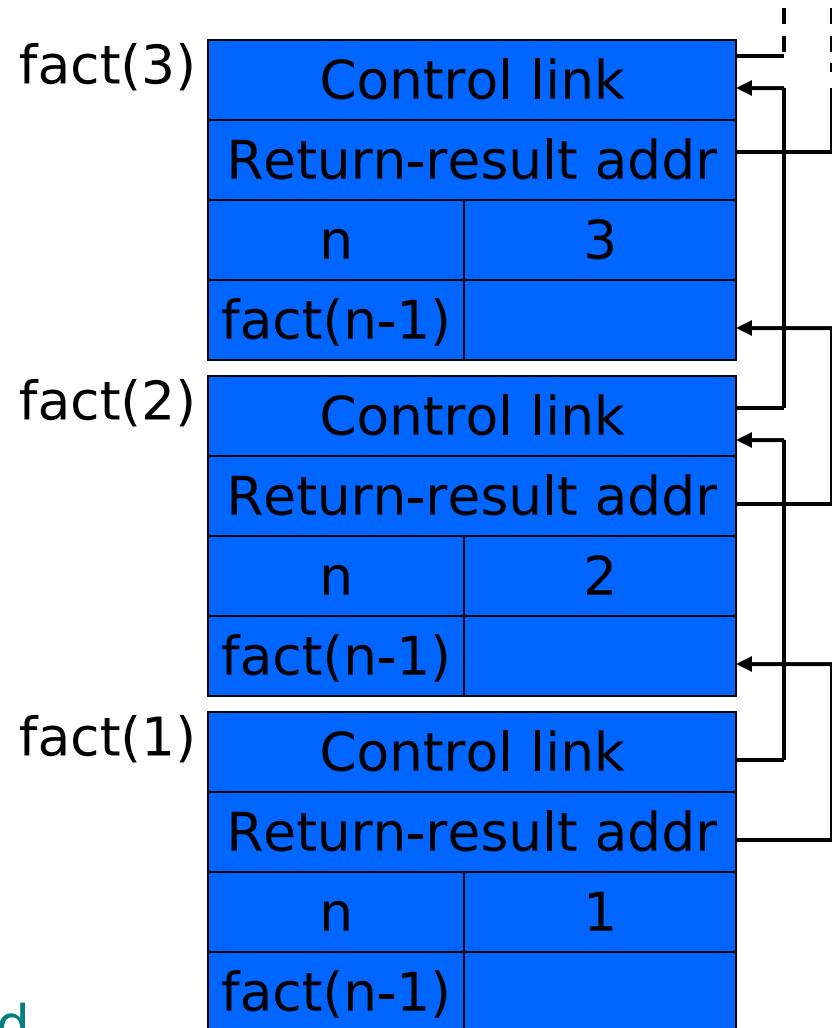

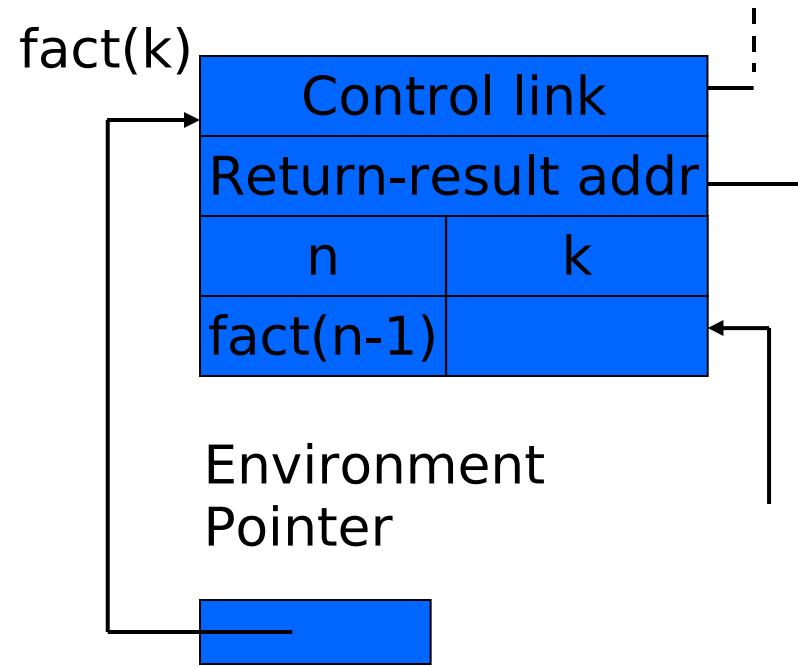

Environment Pointer

Example

- Function
$$\text{fact}(n) = \begin{cases} 1 & \text{if } n \leq 1 \\ n * \text{fact}(n-1) & \text{else} \end{cases}$$
- Return result address
 - location to put $\text{fact}(n)$
- Parameter
 - set to value of n by calling sequence
- Intermediate result
 - locations to contain value of $\text{fact}(n-1)$

Function call

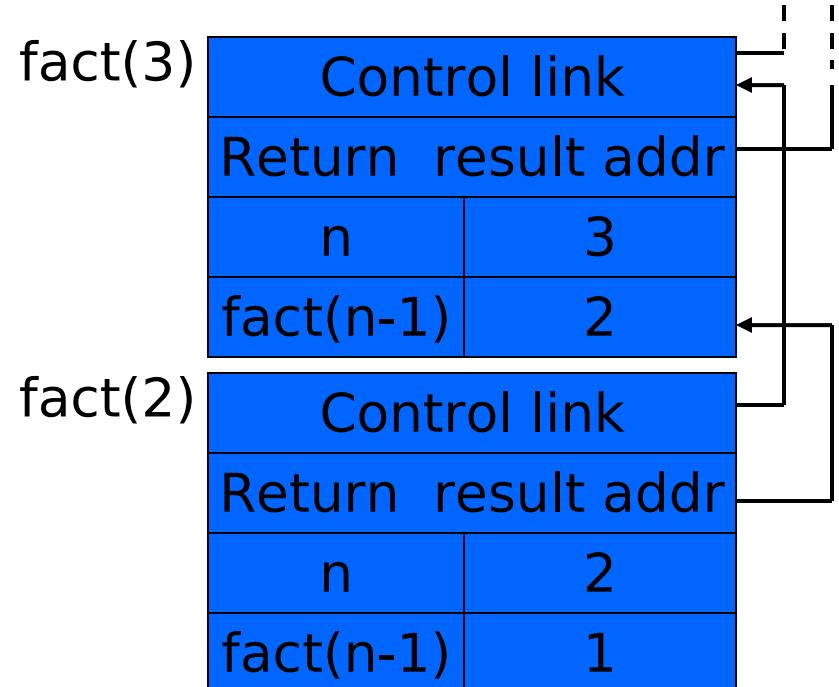

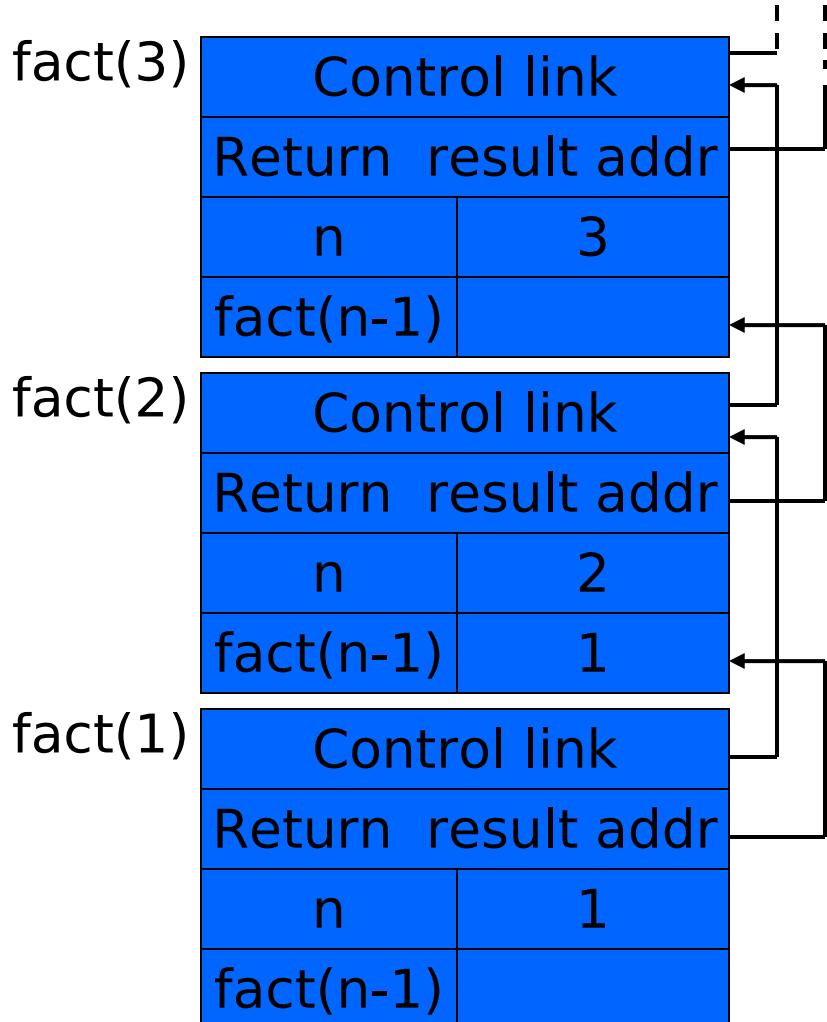

```
fact(n) = if n<= 1  
then 1  
else n *
```

Return address omitted; would
be ptr into code segment

Function return next slide →

Function return

fact(n) = if $n \leq 1$
then 1
else $n * \text{fact}(n-1)$

Topics for first-order functions

- Parameter passing
 - use ML reference cells to describe pass-by-value, pass-by-reference
- Access to global variables
 - global variables are contained in an activation record higher “up” the stack
- Tail recursion
 - an optimization for certain recursive functions

See this yourself: write factorial and run under debugger

ML imperative features (review)

- General terminology: L-values and R-values
 - Assignment $y := x+3$
 - Identifier on left refers to **location**, called its L-value
 - Identifier on right refers to **contents**, called R-value
- ML reference cells and assignment (anche in C++)
 - Different types for location and contents
 - $x : \text{int}$ non-assignable integer value
 - $y : \text{int ref}$ location whose contents must be integer
 - $!y$ the contents
 - $\text{ref } x$ expression creating new cell initialized to x
 - ML form of assignment
 - $y := x+3$ place value of $x+3$ in location (cell) y
 - $y := !y + 3$ add 3 to contents of y and store in location y

Parameter passing

- Pass-by-reference
 - Caller places L-value (address) of actual parameter in activation record
 - Function can assign to variable that is passed
- Pass-by-value
 - Caller places R-value (contents) of actual parameter in activation record
 - Function cannot change value of caller's variable
 - Reduces aliasing (alias: two names refer to same loc)

Example

pseudo-code

```
function f (x) =  
{ x := x+1; return x  
};  
var y : int = 0;  
print f(y)+y;
```

pass-by-ref

pass-by-value

Standard ML

```
fun f (x : int ref) =  
  ( x := !x+1; !x );  
y = ref 0 : int ref;  
f(y) + !y;
```

```
fun f (z : int) =  
  let x = ref z in  
    x := !x+1; !x  
  end;  
y = ref 0 : int ref;  
f(!y) + !y;
```

Example

pseudo-code

```
function f (x) =  
  { x := x+1; return x  
};  
var y : int = 0;  
print f(y)+y;
```

pass-by-ref

pass-by-value

C++

```
int f (int & x) {  
  x = x+1;  
  return x;  
}  
int y = 0;  
cout<< f(y) + y;
```

```
int f (int x) {  
  x = x+1;  
  return x;  
}
```

```
int y = 0;  
cout<< f(y) + y;
```

Passaggio di puntatori

- Il passaggio di puntatori è un passaggio per valore, ma si usa (in C) per ottenere lo stesso effetto del passaggio per riferimento.
- Es.:

```
int f(int* x) {  
    *x = *x+1;  
    return *x;  
}
```

```
int y = 0;  
printf(f(&y) + y;)
```

Se si vuole, si può evitare la modifica del parametro attuale mediante copia:

```
int f(int* x) {  
    int z = *x  
    return z+1;  
}
```

```
int y = 0;  
printf(f(&y) + y;)
```

Parameter passing & activation record

- pass by value: the value of the actual parameter is copied in the activation record as value of the formal parameter
- pass by ref: the address of the actual parameter is copied in the activation record

Osservazioni

- Il passaggio per riferimento ha però alcuni svantaggi:
 - Indirezione ulteriore sullo stack
 - Side effect non desiderati – vedi esercio sul libro
 - Vedi es 7.4
- Passaggio per nome: il nome del par. Formale viene sostituito con il par. Attuale
 - Vedi esercizio 5.2
- Fate esercizi 7.3, 7.5, 7.6, 7.7, 7.8

Access to global variables

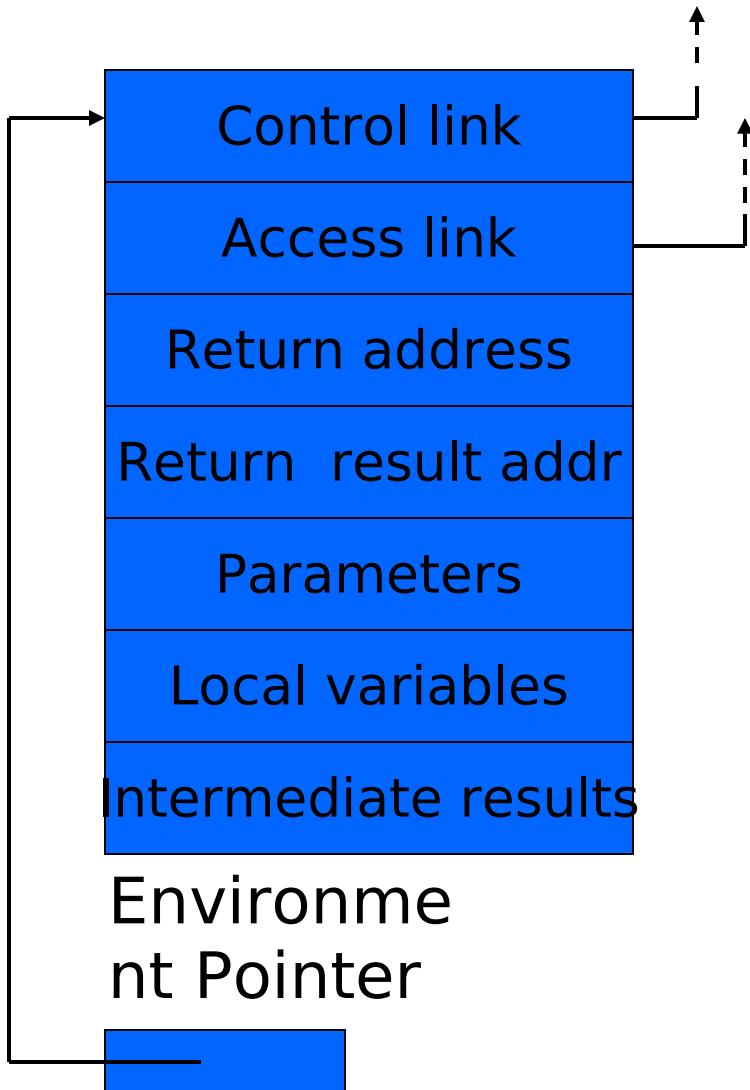

- Two possible scoping conventions
 - Static scope: refer to closest enclosing block
 - Dynamic scope: most recent activation record on stack
- Example

```
int x=1;  
function g(z) = x+z;  
function f(y) =  
{ int x = y+1;  
  return g(y*x) };  
f(3);
```

outer	x	1
block	y	3
f(3)	x	4
g(12)	z	12

Which x is used for expression
 $x+z$?

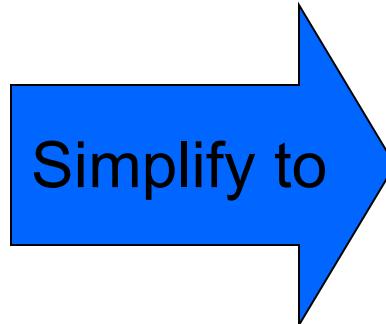

Activation record for static scope

- Control (dynamic) link
 - Link to activation record of previous (calling) block
- Access (static) link
 - Link to activation record of closest enclosing block in program text
- Difference
 - Control link depends on dynamic behavior of prog
 - Access link depends on static form of program text

Complex nesting structure

```
function m(...){  
    int x=1;  
    ...  
    function n( ... ){  
        function g(z) = x+z;  
        ...  
        { ...  
            function f(y) {  
                int x = y+1;  
                return g(y*x) ;  
            ...  
            f(3); ... }  
            ... n( ... ) ...}  
... m(...)
```

```
int x=1;  
function g(z) = x+z;  
function f(y) =  
{ int x = y+1;  
return  
g(y*x) };  
f(3);
```

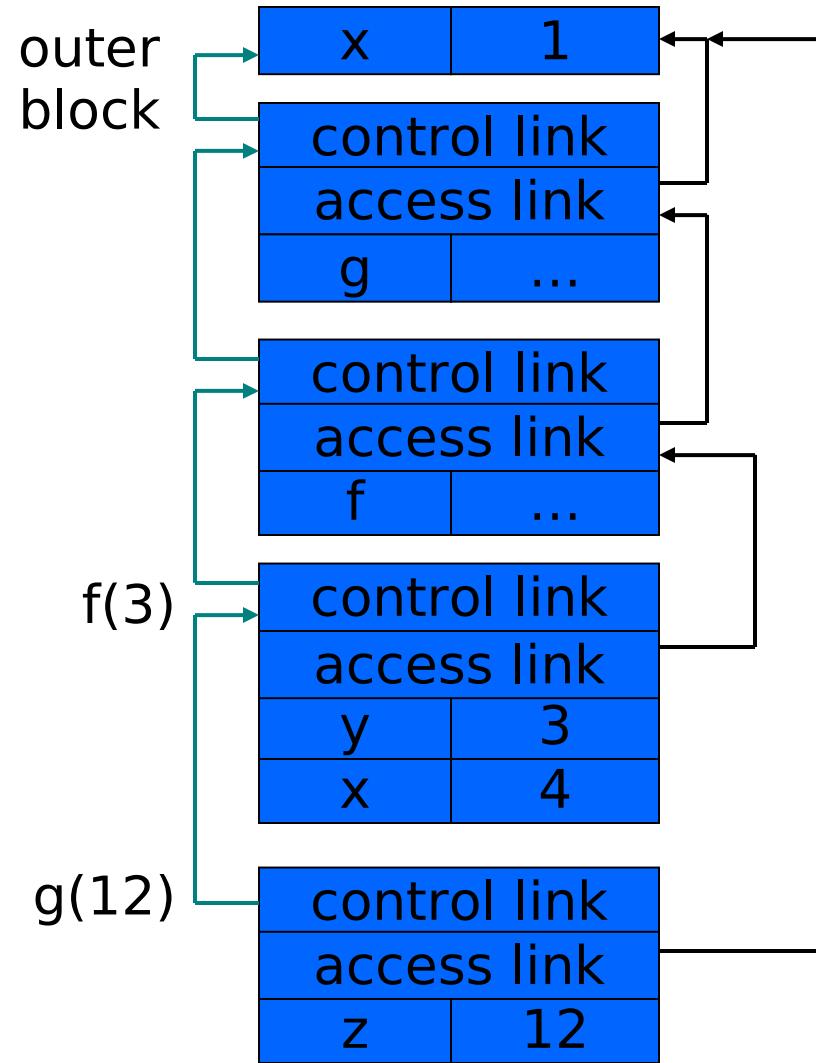

Simplified code has same block nesting,
if we follow convention that each
declaration begins a new block.

Static scope with access links

```
int x=1;  
function g(z) = x+z;  
function f(y) =  
{ int x = y+1;  
  return  
  g(y*x) };  
f(3);
```

Use access link to find global variable:

- Access link is always set to frame of closest enclosing lexical block
- For function body, this is block that contains function declaration

Tail recursion (first-order case)

- Function g makes a *tail call* to function f if
 - Return value of function f is return value of g
- Example

fun g(x) = if x>0 then return f(~~x~~) else return f(x)*2

tail call *not a tail call*

- Optimization
 - Can pop activation record on a tail call
 - Especially useful for recursive tail call
 - next activation record has exactly same form

Example

Calculate least power of 2 greater than y

f(1,3)

control	
return val	
x	1
y	3

```
fun f(x,y) = if x>y  
    then ret x  
    else ret f(2*x, y);  
f(1,3) + 7;
```

control	
return val	
x	1
y	3

control	
return val	
x	2
y	3

control	
return val	
x	4
y	3

Optimization

- Set return value address to that of caller

Question

- Can we do the same with control link?

Optimization

- avoid return to caller

Tail recursion elimination

f(1,3)

control	
return val	
x	1
y	3

f(2,3)

control	
return val	
x	2
y	3

f(4,3)

control	
return val	
x	4
y	3

```
fun f(x,y) = if x>y  
    then x  
    else f(2*x, y);  
  
f(1,3);
```

Optimization

- pop followed by push = reuse activation record in place

Conclusion

- Tail recursive function equiv to iterative loop

Tail recursion and iteration

f(1,3)

control	
return val	
x	1
y	3

f(2,3)

control	
return val	
x	2
y	3

f(4,3)

control	
return val	
x	4
y	3

fun f(x,y) = if x > y
then x
else f(2*x, y);
f(1,y);

test
loop body
initial value

fun g(y) = {
x := 1;
while not(x > y) do
x := 2*x;
return x;
};

Higher-Order Functions

- Language features
 - Functions passed as arguments
 - Functions that return functions from nested blocks
 - Need to maintain environment of function
- Simpler case
 - Function passed as argument
 - Need pointer to activation record “higher up” in stack
- More complicated second case
 - Function returned as result of function call
 - Need to keep activation record of returning function

Summary of scope issues

- Block-structured lang uses stack of activ records
 - Activation records contain parameters, local vars, ...
 - Also pointers to enclosing scope
- Several different parameter passing mechanisms
- Tail calls may be optimized
- Function parameters/results require closures
 - Closure environment pointer used on function call
 - Stack deallocation may fail if function returned from call
 - Closures *not* needed if functions not in nested blocks
