We have seen that, in the context of Information Technology, everything is a number. We have seen how digital images are images mapped onto numbers.

Texts are numbers as well, based the encoding of the characters the texts are comprised of. This is the earliest example of character encoding, which has been and still is expanded throughout the years.

Not really, at least in the real world. Even in the simplest and most rudimentary way of working with numbers, we realize that we have numbers (fingers in the photo) and operations on those numbers (movements of those fingers).

$$3+2$$

When using digits for numbers and symbols for operations, the distinction is clear.

# 352

However, if operations get encoded and hence expressed with numbers, it may get confusing. Is this “threehundredfiftytwo”? We need a clear criterion to deal with numbers that are data and numbers that are operations on such data.

**John Von Neumann**

**1903-1957**

**Von**

The “Von” in his surname may make you think that he comes from a noble German family...

# János Lajos Neumann

...but this is his real name. He was a Hungarian mathematician and physicist, who studied in Hungary and then Switzerland, who fled Hungary when it was invaded by Nazi Germany during World War II.

He fled to the US, where he was a very active member of the team of scientists who worked for the Manhattan project to build a nuclear bomb.

**Nuclear bomb test (Bikini Atoll, Micronesia, 1946)**

He was extremely keen on obtaining the most devastation possible from his experiments, calculating the most effective profile shapes and trajectories of the launched bombs. He proposed to bomb Kyoto, the cultural capital of Japan.

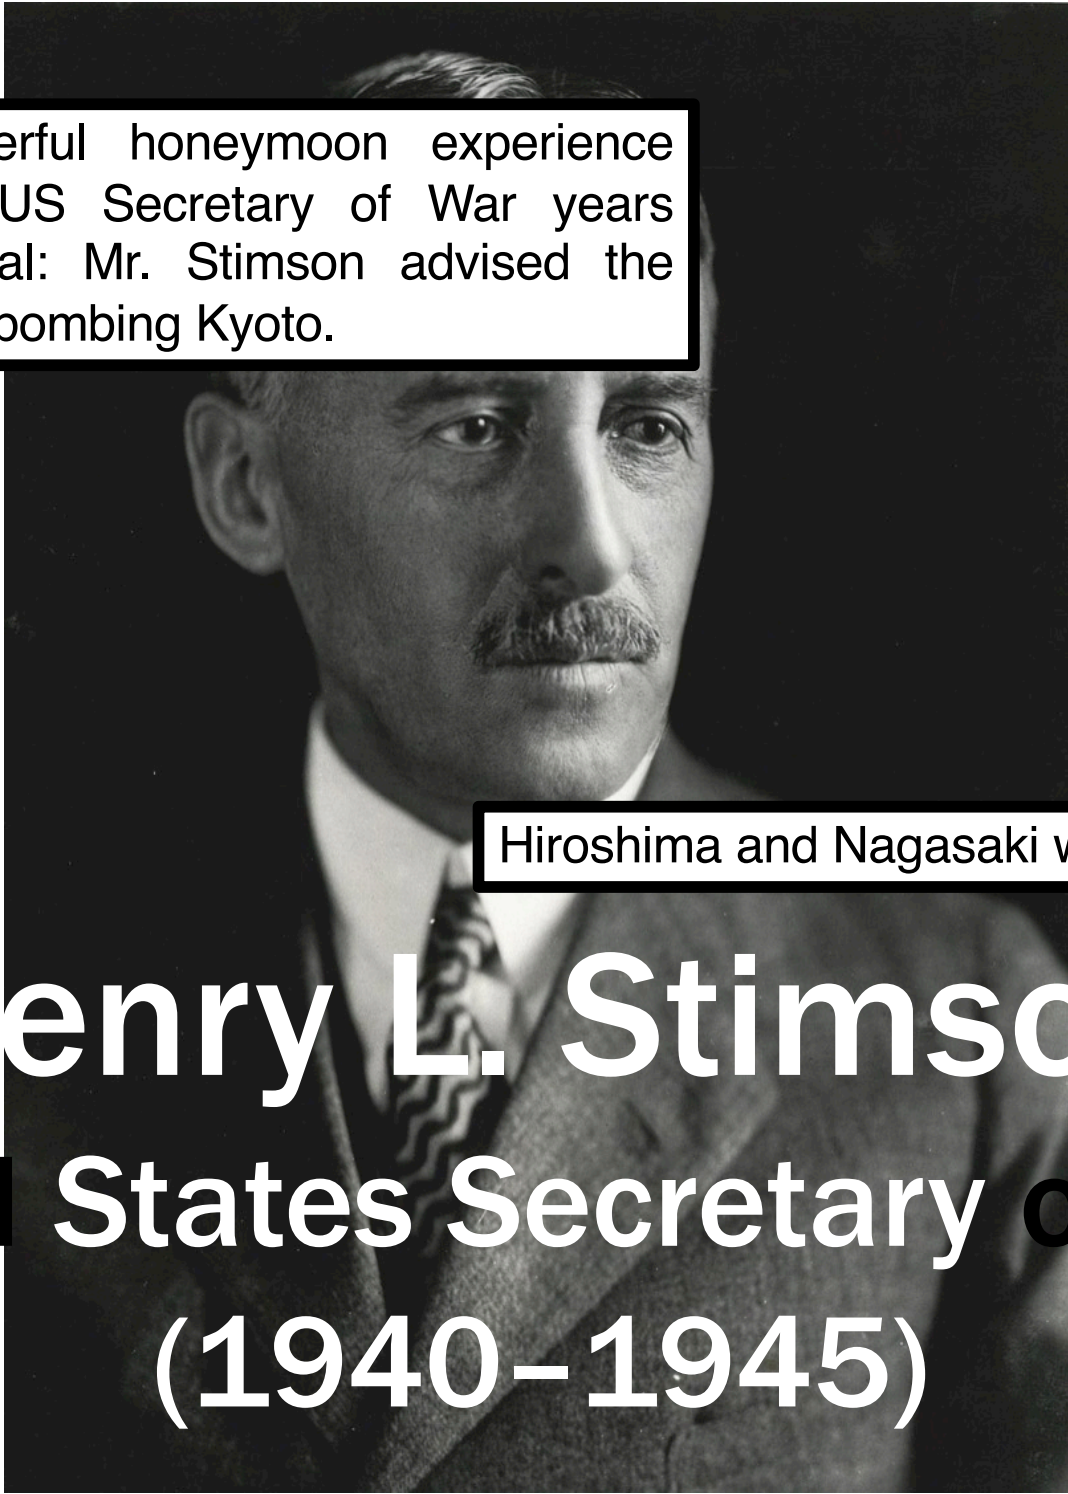

# Honeymoon in Kyoto

Kyoto is an incredibly romantic city. With intimate restaurants, atmospheric lanes, superb accommodations and a thousand quiet gardens and temples, it's the perfect place to spend time with someone you love. Here's our full guide to honeymooning in Kyoto.

This beautiful photo of Kyoto is taken from a website promoting honeymoon trips to the city.

A black and white portrait of Henry L. Stimson, a man with a mustache, wearing a suit and tie. The portrait is the background for the text boxes.

Indeed, a wonderful honeymoon experience enjoyed by the US Secretary of War years before was crucial: Mr. Stimson advised the President against bombing Kyoto.

Hiroshima and Nagasaki were chosen instead.

# Henry L. Stimson

## United States Secretary of War (1940–1945)

Despite his deep convictions on the use of the nuclear bomb (convictions that eventually led him to die of cancer due to radiation exposure), Von Neumann's contribution to computer science is undeniably brilliant.

The merit of the paradigm of data organization inside a computer he proposed needs to be shared with some of his contemporaries, who were working and collaborating with him on the topic.

We are going to color-code the different ways in which data is used inside a computer's memory. Red for operations, blue for operands (i.e. the data to which we apply the operations), green for indicating the locations in the memory where data is stored. These colors are only useful to humans, obviously. No such colorful distinction is possible inside a computer.

# THE MATRIX

It is all based on a matrix-like structure. Not "the matrix" as in the groundbreaking sci-fi movie, but as in the rectangular structure organized in rows and columns, in which every position can be occupied by a piece of data.

These are column indexes

$$\begin{matrix} & \color{red}{1} & \color{red}{2} & \dots & \color{red}{n} \\ \color{green}{1} & a_{11} & a_{12} & \dots & a_{1n} \\ \color{green}{2} & a_{21} & a_{22} & \dots & a_{2n} \\ \color{green}{3} & a_{31} & a_{32} & \dots & a_{3n} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \color{green}{m} & a_{m1} & a_{m2} & \dots & a_{mn} \end{matrix}$$

These are row indexes

The image can be put in a system of coordinates, so that each pixel's position is determined by a pair of numbers (x,y)

We know this way of organizing things already from the way pixels are encoded in digital technology. Actually, the organization of data in a memory predates digital photography.

□ (9,14)

By indexing rows and columns...

...we introduce a matrix of places. Each place can contain one piece of data.

5	7	6	8	1	3	4	9
0	6	7	8	9	0	1	1
2	8	3	5	4	5	7	6
9	8	0	8	7	7	3	9

Computers usually access data row by row, meaning that they do not transfer one single data, but an entire row at a time. Rows inside a computer memory are called “words”.

5	7	6	8	1	3	4	9
---	---	---	---	---	---	---	---

0	6	7	8	9	0	1	1
---	---	---	---	---	---	---	---

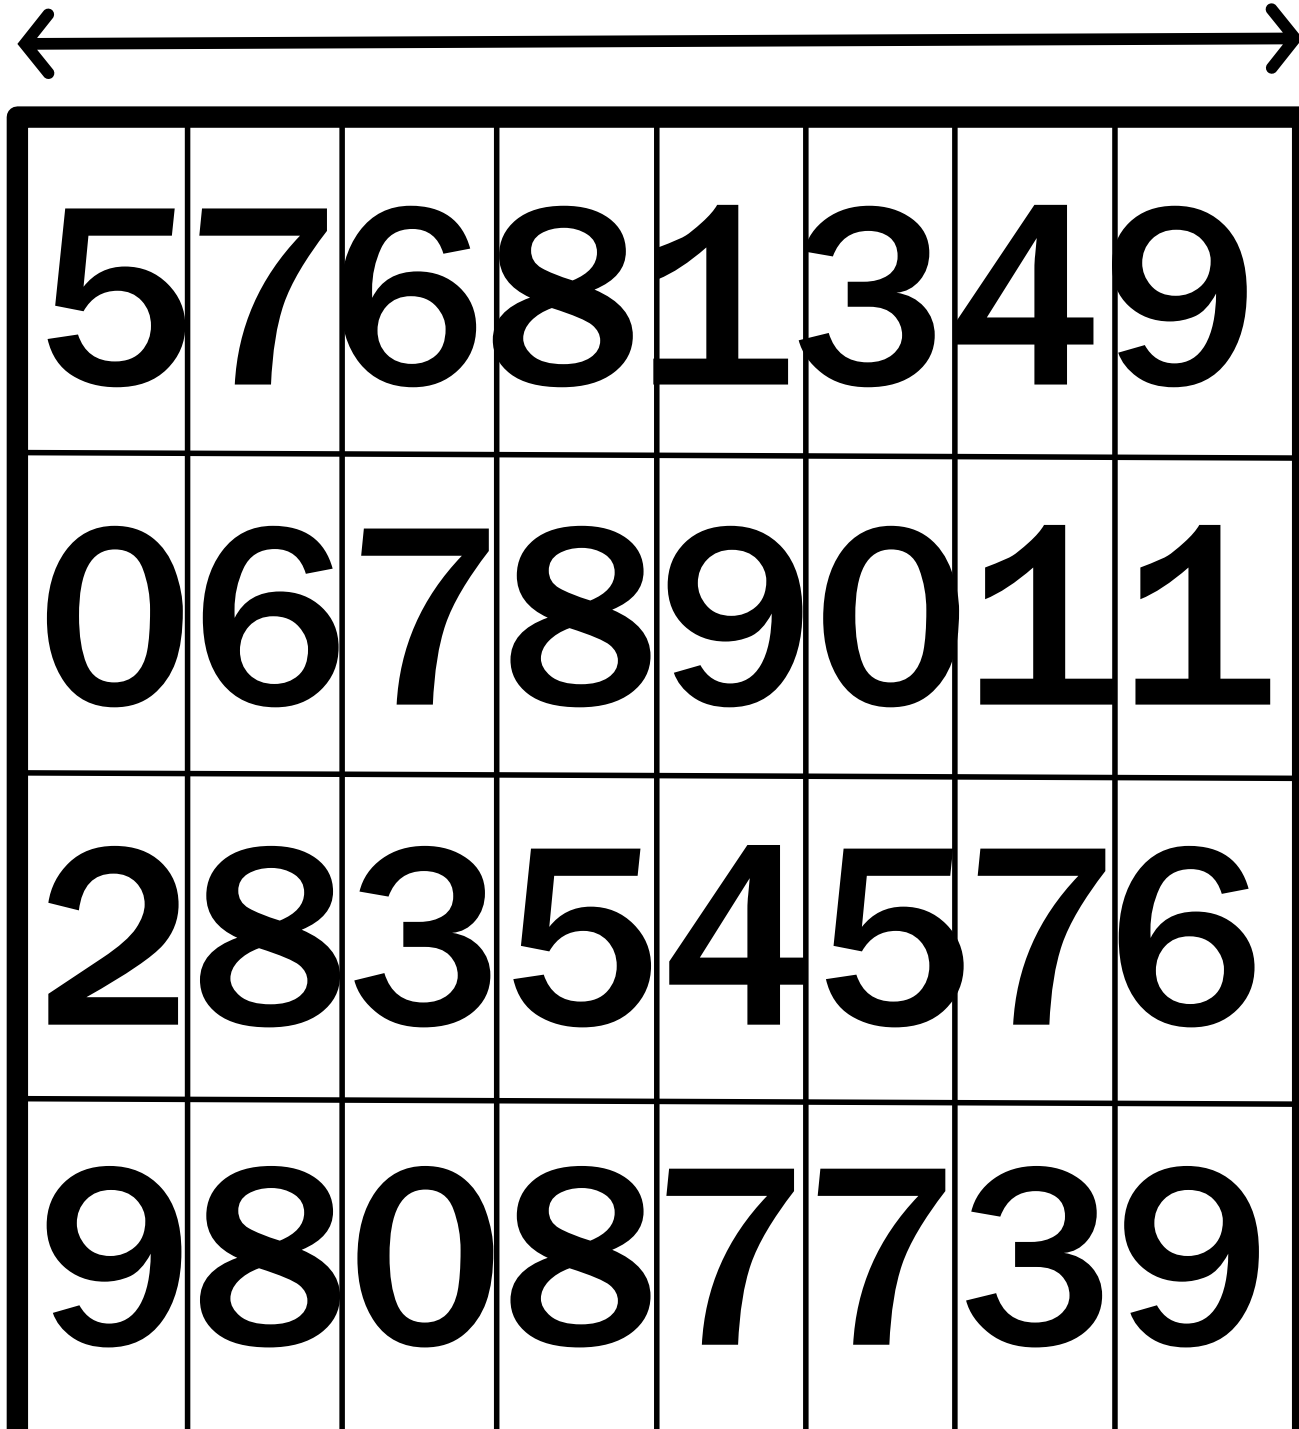

a “word”

5	4	5	7	6
---	---	---	---	---

9	8	0	8	7	7	3	9
---	---	---	---	---	---	---	---

The width of the memory coincides with the length of a row.  
In real computers, each position is not occupied by a digit in the decimal system...

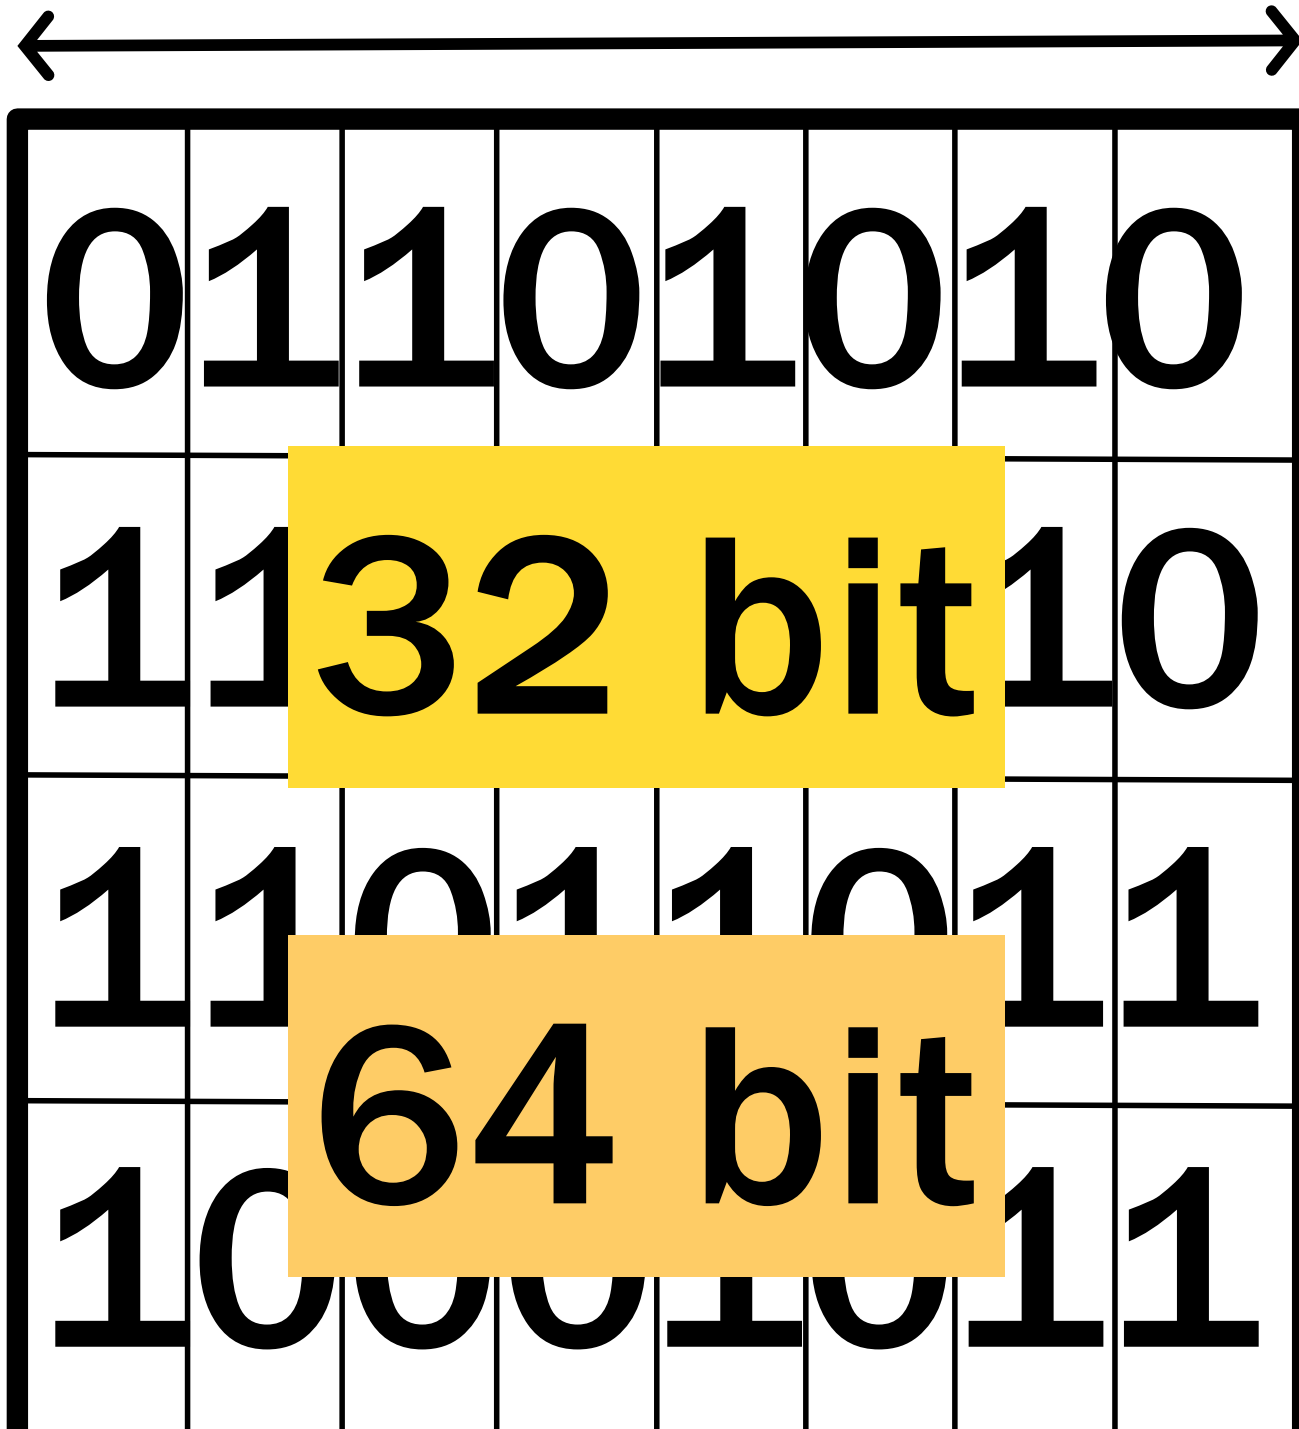

5	7	6	8	1	3	4	9
0	6	7	8	9	0	1	1
2	8	3	5	4	5	7	6
9	8	0	8	7	7	3	9

...but by a bit,  
that is, a  
binary digit (0  
or 1).  
Hence, the  
length of a  
word can be  
measured in  
bits.

<b>0</b>	<b>1</b>	<b>1</b>	<b>0</b>	<b>1</b>	<b>0</b>	<b>1</b>	<b>0</b>
<b>1</b>	<b>1</b>	<b>0</b>	<b>0</b>	<b>1</b>	<b>1</b>	<b>1</b>	<b>0</b>
<b>1</b>	<b>1</b>	<b>0</b>	<b>1</b>	<b>1</b>	<b>0</b>	<b>1</b>	<b>1</b>
<b>1</b>	<b>0</b>	<b>0</b>	<b>0</b>	<b>1</b>	<b>0</b>	<b>1</b>	<b>1</b>

Most common computers today contain memories that are 32 or 64 bit in width. Such width determines the size of a single piece of data that the computer can transfer from and to its memory.

Don't forget that a bit is the smallest data size: it is a 0 or a 1. A sequence of 8 bits forms a byte. Bits are indicated with 'b', bytes with 'B'.

Now that we have organized the memory as a matrix of places for bits...

# Again, choices.

The position of the division is arbitrary. It is all about programming the computer in a way

All bits inside the memory are the same from a physical perspective, but depending on where they are, they are used in different ways.

<b>0</b>	<b>1</b>	<b>1</b>	<b>0</b>	<b>1</b>	<b>0</b>	<b>1</b>	<b>0</b>

# THE STORED PROGRAM

Both operations and operands can be stored in the same place.

# THE STORED PROGRAM

Both operations and  
operands are bits  
stored inside words.

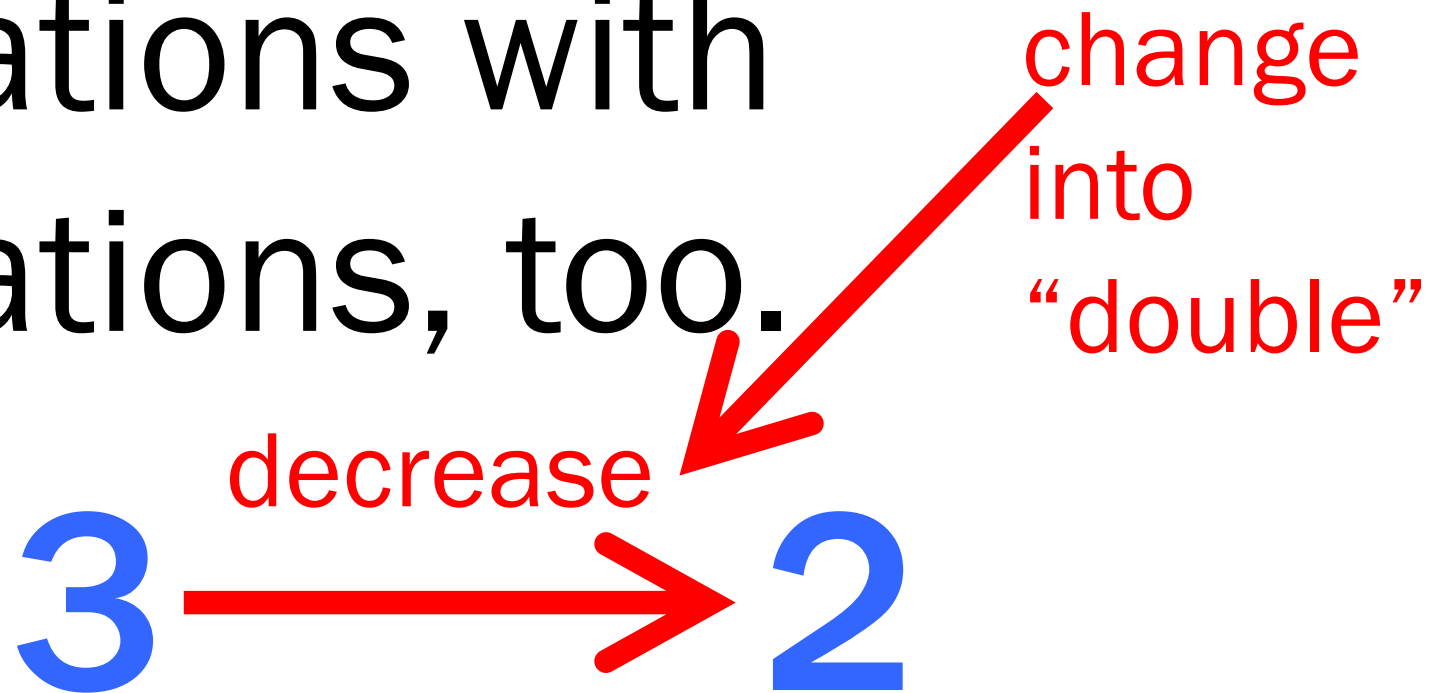

# THE STORED PROGRAM

We manipulate

operations.

# THE STORED PROGRAM

We can manipulate operations with operations, too.

# THE STORED PROGRAM

We can manipulate  
operations with  
operations, too.

**Master of  
Manipulation**

We still have to deal with the issue of knowing where these operations and operands are placed inside the memory. We know, inside a word, which part is occupied by the operation and which part by the operands, but we still need a way to express where that word is inside the memory.

operations

operands

place 352

We need a way to refer to each word in the memory.

<b>0</b>	<b>1</b>	<b>1</b>	<b>0</b>	<b>1</b>	<b>0</b>	<b>1</b>	<b>0</b>
<b>1</b>	<b>1</b>	<b>0</b>	<b>0</b>	<b>1</b>	<b>1</b>	<b>1</b>	<b>0</b>
<b>1</b>	<b>1</b>	<b>0</b>	<b>1</b>	<b>1</b>	<b>0</b>	<b>1</b>	<b>1</b>
<b>1</b>	<b>0</b>	<b>0</b>	<b>0</b>	<b>1</b>	<b>0</b>	<b>1</b>	<b>1</b>

We rely on the indexes of the matrix. Since rows are deal with as words, we can focus on the row indexes and forget about the column indexes.

0	0	1	1	0	1	0	1	0
1	1	1	0	0	1	1	1	0
2	1	1	0	1	1	0	1	1
3	1	0	0	0	1	0	1	1

Since these indexes work like addresses of each word, we call them so.  
Each word has an address.

0	0	1	1	0	1	0	1	0
1	1	1	0	0	1	1	1	0
2	1	1	0	1	1	0	1	1
3	1	0	0	0	1	0	1	1

**Addresses**

Depending on how many bits we use for each address, the number of words we can assign an address to varies. If we use 4 bit (like in this slide), we have a range of addresses from 0000 to 1111. A total of 16 addresses, which means that the addressable memory can only have 16 words.

0000

01101010

0001

11001110

0010

11011011

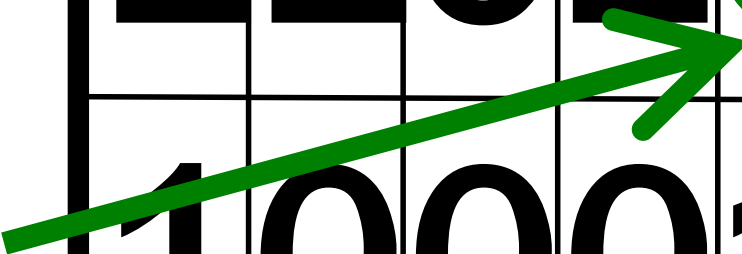

0011

10001011

If we used 32 bits to compose addresses, then we could address up to  $2^{32}$  words, that is, more than 4 billion words.

Since addresses are also bits, they can be stored inside the memory as data, and become a parameter of some operations, like “assign 5 to x”, where x is the address of the destination word.

0000	0	1	1	0	1	0	1	0
0001	1	1	0	0	1	1	1	0
0010	1	1	0	1	0	0	1	1
0011	1	0	0	0	1	0	1	1

Hence, all sorts of data can be stored inside the memory: operations to perform, operands to perform operations to, and the addresses of the words where these operations and these operands are written.

“File” is a term we borrow from  
real life, inside an office.

A file cabinet.

Here is a person who manages  
the file cabinet in an office.

The image is one of many results of an image search with the keywords “secretary file cabinet.”

If you notice a stereotype in the images, do not blame the search technology: it just gives you what is available online. If what is online is problematic and search technology makes us keep on working with what is online, then the problem gets amplified and extended by Information Technology (this is a foreshadowing of current and future problems between society and technology).

# Where is **w**?

# FILES

- A file is a group of bits that are **logically** treated as a unit.
- A file may be comprised of data, program instructions, or addresses.

“Logical” in the context of files does not mean that it is connected to solid and elemental reasoning; it means “abstract” as opposed to “physical”.

A file is “logically” treated as a unit, but in the physical reality of the memory, it may be fragmented in different parts, distributed throughout the memory. The file system sees to it that the users of the computer do not notice this fragmentation.

What is a file of addresses? It is actually a very familiar thing.

The folders that the File System of your computer shows you, are actually files containing addresses of other files (the ones that are metaphorically “contained” in the folder).
